Abstract

A field experiment carried out at the experimental area of the El-kantera shark, north Sinai, Egypt, during season of 2017/2018 to study the effect of four potassium fertilization rates (0, 15, 30 and 45 kg K2O/fed as potassium sulphate (50% K2O) and four treatments of organic materials (without organic, humic, fulvic, compost), humic and fulvic added rate of 30 kg/fed; meanwhile compost added rate of 10 ton/fed, on straw, seeds, pods, either nutrients content and uptake by faba bean in sandy soil. The obtained results showed that application of the potassium fertilization and sources of organic materials added to soil alone or in combination with each other led to significantly increase of dry of straw, seeds, pods (g/plant), plant height, (cm). In addition, the nitrogen, phosphorus, potassium and some micronutrients uptake of seeds in faba bean significantly increase with increasing K fertilization a combined with source of organic materials, the highest values was recorded with the treatments of 45 kg K2O/fed with humic acid. This may be attributed to the influence of potassium addition on K availability in soil; Moreover the effect of potassium in plant metabolism which increases nutrient absorption. Generally, from these results it can be concluded that the application of potassium fertilization rates and organic materials sources improved all growth characteristics and nutrients uptake of faba bean plant.

Key words: Potassium fertilizer, humic substance, nutrients uptake, plant.

Introduction

Potassium plays a vital role as a macronutrient in plant growth and sustainable crop production (Baligar et al., 2001). It maintains turgor pressure of cell which is necessary for cell expansion. It helps in osmo-regulation of plant cell, assists in opening and closing of stomata. It plays a key role in activation of more than 60 enzymes (Bukhsh et al., 2011). Goals aimed toward increasing crop productivity and improved quality dictate either increased potassium supply or more efficient use of potassium. Developing plants that more efficiently use potassium might be a worthwhile goal for geneticists (Pettigrew, 2008). Also, potassium element is very important in overall metabolism of plant enzymes activity, it was found to serve a vital role in photosynthesis by direct increasing in growth and total yield. Also, potassium has a beneficial effect on water consumption (Mansour, 2006); Mansour and Aljughaiman (2012, 2015); Mansour et al., (2014, 2016). Taha et al., (2016) who found that, the EC and pH of soil was decreased with increasing rates of potassium sources. The available nutrients in soil (N, P, K and Fe) increased significantly with increasing rates of potassium fertilizers. Nataraajan and Renukadevi (2003) studied the effect of potassium fertilization rate on yield of sorghum, they found that potassium fertilization at all rates increased yield. Ali and Mowafy (2003) found that adding potassium fertilizer caused significant increase in seed yield and all their attributes.

Ferrara and Brunetti (2010) who reported that, the application of humic acid significantly increased width and weight of berries collected at harvest with respect to the control treatment; as well as increase nutrient uptake by the grapevines berry quality of table grape. While, Magdi et al., (2011) reported that, bio-fertigation of microbial inoculums and humic substances could be used as a complementary for mineral fertilizers to improve yield and quality of cowpea under sandy soil conditions. Also, Arancon et al., (2006) showed that the humic acid from vermin composts can enhance nutrient availability and improve chemical, biological, and physical soil properties. Similarly, Meganid et al., (2015) who found that, the humic acid supply significantly increased the relative growth rates of shoot and root under saline conditions and humic is considered as a promising soil amendment to overcome adverse effects of salinity stress.

The direct and indirect beneficial effects of humic acid on plant growth and development are their effect on cell membranes which lead to the enhanced transport of minerals, improved protein synthesis, plant hormone-like activity, promoted photosynthesis, modified enzyme activities, solubility of micro-elements and macro-elements, reduction of active levels of toxic
minerals and increased microbial populations, (Hamideh et al., 2013). Benefits ascribed to the use of humic acid, particularly in low organic matter, alkaline soil, include increased nutrient uptake, tolerance to drought and temperature extremes, activity of beneficial soil microorganisms and availability of soil nutrients (Russo and Berlyn, 1990). Humic acid are the main fraction of humic substances and the most active components of soil and compost organic matter. Humic acid can enhance nutrient availability and improve chemical, biological, and physical soil properties (Selim et al., 2009). Meanwhile, Nardi et al. (2002). Stated that, the effects of humic substances on plants, results show that, the, humic acid can enhance nutrient availability and improve chemical, biological, and physical soil properties. Selimand and Mosa, (2012) stated that, effect of humic substances on yield and quality of broccoli and nutrient retention in a sandy soil. Results indicated that, humic acid can enhance nutrient availability to plant and improve chemical, biological, and physical soil properties.

The main goals of this study the effect of organic materials with potassium rate under water drip irrigation system on yield and nutrients uptake by faba bean plant.

The soil sample was routinely analyzed according to (Klute, 1986) and (Page et al., 1982) the results are presented in Table 1. Plant analysis; total nitrogen was determined using Kjeldahl method,
phosphorus was determined colorimetrically, potassium by flame photometer Page et al. (1982). The micronutrients (Fe; Mn and Zn) were determined by Inductively Coupled Plasma Spectrometer (ICP) Plasma 400. Statistical analysis: finally all obtained data were subjected to analysis of variance and treatment means were compared by L.S.D. test at the 5% level of probability in the experimented season according to Gomez and Gomez (1984).

**Results and Discussion**

**Dry Matter Yields (Straw and Seeds)**

Data presented in Table 3 show that the dry matter yield of straw and seeds were significantly affected by application of potassium rates and source of organic materials at all treatments; and the highest values of dry matter yield were recorded with 45kg fed-1 potassium sulphate with humic acids compared with the other treatments and the control. The highest values were 19.27 and 12.82 g/plant in straw and seeds respectively. The effect of potassium sulphate in the soil may be attributed to the role of sulphate in potassium sulphate played by this acidic component for minimizing the values of soil pH and, subsequently facilitate the absorption of nutrients by the roots of faba beans plants. The positive effects of humic substances on yields have demonstrated the importance of optimum mineral supply, independent of nutrition. These results are in a partial agreement with those obtained by Nardi et al. (2002). Stated that, the effects of humic substances on plants, results indicated that the, humic acid can enhance nutrient availability and improve chemical, biological, and physical soil properties. In addition, Natarajan and Renukadevi (2003) studied the effect of potassium fertilization rate on yield of sorghum, they found that potassium fertilization at all rates increased yield. Also, Ali and Mowafy (2003) found that adding potassium fertilizer caused significant increase in seed yield and all their attributes.

Dry weight of pods, seeds, height plant and dry weight of 100 seeds: With regard to the effect of using potassium fertilization rates and source of organic materials on growth parameter data in Table
3 reveal that the mean values of pods, seeds (g/plant), height plant (cm) and dry weight of 100 seeds of faba bean plant were significantly increase with increasing K-rate with all source of organic materials. The highest values were observed with adding recorded with 45kg fed\(^1\) potassium sulphate with humic acids compared with the other treatments and the control. These results could be attributed to the role of potassium element in metabolism and many processes needed to sustain and promote plant vegetative growth and development. Moreover, K plays a major role in many physiological and biochemical processes such as cell division and elongation and metabolism of carbohydrates and protein. These results are in harmony with those obtained by (McDonnell et al., 2001) humic substances are an important soil component because they constitute a stable fraction of carbon, improve water holding capacity and pH buffering; which increases nutrient absorption leading to the increase in dry weight. In addition Mansour (2006) who indicated that, potassium element is very important in overall metabolism of plant enzymes activity, it was found to serve a vital role in photosynthesis by direct increasing in growth and total yield.

Macronutrients content and uptake by faba bean plant beam plant increased with increasing K application; N, P and K uptake (mg/plant) significantly increase with increasing K fertilization a combined with source of organic materials, the highest values was recorded with the treatments of 45 kg K\(_2\)O/fed with humic acid. This may be attributed to the influence of potassium addition on K availability in soil; Moreover the effect of potassium in plant metabolism which increases nutrient

Data presented in Table 4 show that, the effect of potassium fertilization on N, P, K and protein content (%) in seeds of faba bean plant; the increasing of K application led to increasing N, P, K and protein content (%) in straw and seeds of faba bean plant; as well as the NPK uptake (mg/plant) in straw and seeds by faba bean
absorption. These results are in harmony with those obtained by Selim et al. (2009) who found that, that, humic acid can enhance nutrient availability and improve chemical, biological, and physical soil properties. Meanwhile, Hussien (2007) reported that potassium application (up to 30 kg/fed) significantly increased N content (%) of canola plants.

Micronutrients content and uptake by faba bean plant

Regarding the effect of using potassium fertilization rates and source of organic materials on some micronutrients µg/plant (Fe, Mn and Zn) data in Table 3 show that, the uptake of this nutrients in seeds by faba bean plant increased with increasing K application. Fe, Mn and Zn uptake (µg/plant) significantly increase with increasing K fertilization a combined with source of organic materials, the highest values was recorded with the treatments of 45 kg K2O/fed with humic acid. This may be attributed to the influence of potassium addition on K availability in soil; Moreover, the effect of potassium in plant metabolism which increases nutrient absorption. These results are in harmony with those obtained by Russo and Selim (2009). Application of humic substances have been shown to increase membrane permeability, photosynthesis, some nutrients uptake, nitrogen use efficiency and root elongation.

### Conclusion

Results obtained in the present work confirmed that organic materials specific of humic acid was able to produce some positive effects in faba bean (Vicia faba L.). In particular, significant improving characteristic of plant growth, nutrients content and uptake by plant, the highest values have been observed due to humic acid application with rate potassium fertilizers.
