ABSTRACT

To investigate the effect of different organic nutrient sources on growth, chlorophyll content and dry matter production of barnyard millet (Echinochloa frumentacea (Roxb.) Link) in sandy loam soil, a pot experiment was conducted at the Department of Soil Science and Agricultural Chemistry, Annamalai University during February-May, 2019. The weather at Annamalainagar was moderately warm with hot summer. The experiment was laid out in completely randomized block design (CRD) with nine treatments and three replications. The treatments of the study were T1 – Control, T2 –100% RDF, T3 – Coir pith compost @ 10 t ha-1, T4 – Bone meal powder @ 1 t ha-1, T5 – Panchagavya @ 3 % (Foliar spray), T6 –T3 + T4, T7 – T4 + T5, T8 – T3 + T5 and T9 – T3 + T4 + T5. The results revealed that application of 100% RDF (N: P2O5: K2O @ 40:30:50 kg ha-1) (T2) recorded the highest plant height of 159.74 cm, number of leaves plant-1 (8.51), leaf area index (3.12), chlorophyll content (49.14) and dry matter production (472.30 g pot-1) at harvest stage. These were on par with T9 – CPC + BMP + PG.

Keywords: barnyard millet, Echinochloa frumentacea (Roxb.), coir pith compost, bone meal powder, panchagavya

INTRODUCTION

Millet are still the principal sources of energy, protein, vitamins and minerals for millions of poorest people. India is one of the major producers of millets in the world. The total production of minor millets in India is 6.83 lakh hectares with an average productivity of 630 kg ha⁻¹. (Agriculture statistics at a glance, 2015). The area under barnyard millet in India is about 1.95 lakh hectares and production of 1.67 million tonnes with a productivity of 857 kg ha⁻¹ (Rashmi Yadav et al., 2011). It is a rich source of protein (11.8%) and crude fibre (9.8%). Out of the total protein, it consists of 16.6% of amino acid (leucine), which is twice the quantity of rice, which is highly digestible and is an excellent source of dietary fiber. In recent years there is a huge awareness among people about healthy, nutritive millets and there is a demand for barnyard millet due to its nutritional quality and better adaptability. The spongy structure of coir pith facilitates retention of water in soil and slow release of nutrients. Bone meal is a mixture of finely and coarsely ground animal bones and slaughter-house waste products. It is a organic fertilizer rich in 12 to 16% of phosphorus. Panchagavya is an organic product has the potential to play a role of promoting growth and providing immunity in plant system thereby confers resistance against pest and disease. It contains several nutrients i.e., macronutrients like N, P, K and micronutrients which are required for the growth and development of plant (Ragavendra et al., 2014). This study aimed to assess the impact of integrated organic nutrient sources on growth parameters, chlorophyll content and dry matter production of barnyard millet.

MATERIALS AND METHODS

The present investigation was carried out to find out the effect of different organic nutrient sources on growth, chlorophyll content and dry matter production of barnyard millet (Echinochloa frumentacea (Roxb.) Link) in sandy loam soil through pot experiment was conducted at the Department of Soil Science and Agricultural Chemistry, Faculty of Agriculture, Annamalai University, Annamalainagar during February-May, 2019. It is situated at 11°24’ North latitude and 79°41’ East longitude and at an altitude of +5.79 m above mean sea level. The weather at Annamalainagar is moderately warm with hot summer. The experiment was laid out in completely randomized block design (CRD) with nine treatments and three replications. The treatments are as follows: T1– Control, T2 –100% RDF, T3 – Coir pith compost @ 10 t ha⁻¹, T4 – Bone meal powder @ 1 t ha⁻¹, T5 – Panchagavya @ 3 % (Foliar spray), T6 –T3 + T4, T7 – T4 + T5, T8 – T3 + T5 and T9 – T₃ + T₄ + T₅. Cement pots with the size of 45 x 30 x30 cm were used in the study and each pot was filled with 40 kg of processed soil. Recommended dose of N, P₂O₅ and K₂O for barnyard millet is 40:30:50 kg ha⁻¹. The calculated quantity of NPK fertilizers were applied for the particular treatment on dry weight basis. The organic nutrient sources viz., coir pith compost and bone meal were applied @ 10 and 1.0 t ha⁻¹, respectively to the respective treatment. Panchagavya also applied as per...
the treatment as seed treatment, seedling treatment and foliar spray @ 3%. The crop was grown up to maturity with proper care. Biometric observations viz., plant height, number of leaves plant⁻¹, leaf area index recorded at 30, 60 DAS and at harvest stages. At harvest dry matter production also recorded with different treatments.

RESULTS AND DISCUSSION

Plant height (cm)

The data on plant height (cm) and number of leaves plant⁻¹ of barnyard millet as influenced by different treatments at different growth stages are presented in table 1.

30 DAS

Plant height was significantly highest due to application of 100% RDF (T₂) (51.21 cm). It was on par with application of T₉ – CPC+BMP+PG registered the plant height of 50.76 cm. Application of coir pith compost (T₃), bone meal powder (T₄) and panchagavya (T₅) recorded the plant height of 30.92, 26.96 and 32.01 cm, respectively. However, lowest plant height of 24.25 cm was observed under control (T₁).

60 DAS

Application of 100% RDF (N: P₂O₅: K₂O @ 40:30:50 kg ha⁻¹) (T₂) recorded the highest plant height of 117.31 cm was on par with T₉ – CPC+BMP+PG (113.87 cm). Application of CPC+BMP (T₆), BMP+PG (T₇) and CPC+PG (T₈) recorded the plant height of 84.93, 80.74 and 101.62 cm, respectively. The treatment T₆ was on par with T₇.

At harvest

The plant height recorded by all treatments ranged from 93.61 cm to 159.74 cm. The lowest plant height 93.61 cm was recorded in control (T₁) which received no organic and inorganic fertilizers. Application of 100% RDF (T₂) registered the plant height of 159.74 cm was found to be on par with T₉ – 100% RDF (T₂) and control (T₁). Application of coir pith compost, bone meal powder and panchagavya (T₉) registered the number of leaves plant⁻¹ of 11.55. The treatment T₂ was on par with T₉.

In pot experiment, the highest number of leaves plant⁻¹ on 30 DAS, 60 DAS and at harvest stage were 8.51, 10.70 and 11.61 recorded in T₂ (100% RDF). This was due to soil application of macro nutrients might have favoured better absorption of nutrients resulted in increased number of leaves plant⁻¹. A similar result was reported by Kumar et al., (2015) in pear millet.

Leaf area index

The data on leaf area index significantly differed due to treatments at different growth stages are presented in table 2.

30 DAS

Significantly the highest leaf area index of 2.61 was noticed in T₂ - 100% RDF. It was on par with application of coir pith compost, bone meal powder and panchagavya registered the leaf area index of 2.54. The treatment T₂ was on par with T₉. However, the lowest leaf area index (1.10) was observed under control (T₁).

At harvest

The maximum and minimum leaf area index of 2.61 was noticed in T₂ - 100% RDF. It was on par with application of coir pith compost, bone meal powder and panchagavya registered the leaf area index of 2.54. The combined application of coir pith compost, bone meal powder and panchagavya (T₉) registered the leaf area index of 2.54. The treatment T₂ was on par with T₉. However, the lowest leaf area index (1.10) was observed under control (T₁).

60 DAS

Significantly highest leaf area index of 2.61 was noticed in T₂ - 100% RDF. It was on par with application of coir pith compost, bone meal powder and panchagavya registered the leaf area index of 2.54. The treatment T₂ was on par with T₉. However, the lowest leaf area index (1.10) was observed under control (T₁).

At harvest

Similar above trend was observed at harvest stage of barnyard millet. Significantly highest leaf area index (3.12) was obtained with T₂ - 100% RDF. Application of coir pith compost (T₂), bone meal powder (T₄) and panchagavya (T₅) found to be on par with application of coir pith compost, bone meal powder and panchagavya (T₉) (8.48). However, the number of leaves plant⁻¹ was minimum of 7.39 noticed in T₁ control.

60 DAS

Application of 100% RDF (N: P₂O₅: K₂O @ 40:30:50 kg ha⁻¹) (T₂) recorded the highest number of leaves plant⁻¹ of 10.70 the treatment T₂ was on par with T₉ – CPC + BMP + PG (10.54). Application coir pith compost (T₉), bone meal powder (T₄) and panchagavya (T₅) registered the number of leaves plant⁻¹ were 8.71, 8.38 and 8.75, respectively. Significantly lowest number of leaves plant⁻¹ of 8.05 was observed with control treatment (T₁).
Effect of coir pith compost, bone meal powder and panchagavya on growth, chlorophyll content and dmp of barnyard millet

**Fig.1.** Plant height of barnyard millet cv. CO2 at different stages as influenced by in organic fertilizers, coir pith compost, bone meal powder and panchagavya in pot-culture experiment.

**Table 1:**

Panchagavya (T<sub>5</sub>) recorded the leaf area index of 2.50, 2.32 and 2.47, respectively. However, the leaf area index was lowest (2.18) found to be with control (T<sub>1</sub>). This might be due to fertilizer application in particular nitrogen helps maintenance of higher number of leaf, leaf area and leaf area index. The results are in conformity with the finding of Reddy (1999).

**Chlorophyll content**

**30 DAS**

Application of 100%RDF (N: P<sub>2</sub>O<sub>5</sub>; K<sub>2</sub>O @ 40:30:50 kg ha<sup>-1</sup>) (T<sub>2</sub>) recorded the highest chlorophyll content of 42.64 was on par with 41.95 observed in T<sub>9</sub> which received the combined application of coir pith compost, bone meal powder and panchagavya. Application of coir pith compost (T<sub>3</sub>), bone meal powder (T<sub>4</sub>) and panchagavya (T<sub>5</sub>) registered the chlorophyll content of 39.31, 37.84 and 38.16, respectively. However, the lowest chlorophyll content (37.51) was found to be with control (T<sub>1</sub>).

**60 DAS**

The maximum chlorophyll content of 54.93 was significant due to application of 100%RDF (T<sub>2</sub>). It was on par with T<sub>9</sub> – CPC + BMP + PG recorded the chlorophyll content of 53.75. The combined application of CPC+BMP (T<sub>6</sub>), BMP+PG (T<sub>7</sub>) and CPC+PG (T<sub>8</sub>) recorded the chlorophyll content of 49.17, 47.18 and 51.16, respectively.
However, the chlorophyll content was minimum (42.62) noticed in T1 – Control which received no organic nutrient sources and inorganic fertilizers.

**At harvest**

Similar above trend was also observed at harvest stage of barnyard millet. Significantly highest chlorophyll content (49.14) was noticed in T2 which received 100% RDF (N:P2O5:K2O @ 40:30:50 kg ha⁻¹). It was on par with T9 (47.88) which received the combined application of coir pith compost, bone meal powder and panchagavya. However, the control registered the lowest chlorophyll content of 32.60.

This might be due to increase in chlorophyll content of plants by efficient utilization of resources such as solar energy, moisture and nutrients. The higher rate of nitrogen application also increased the chlorophyll content of the plant (Hokmalipour and Darbandi, 2011). This was also due to increased availability of nitrogen which is a main constituent of chlorophyll with increase in the dose of fertilizer.

**Dry matter production**

Significantly the highest dry matter production (472.30 g pot⁻¹) was obtained in T2 – 100%RDF. It was followed by 464.79 g pot⁻¹ was found to be with combined application of coir pith compost, bone meal powder and panchagavya (T9). The treatment T9 was on par with T7. Application of coir pith compost (T7), bone meal powder (T8) and panchagavya (T10) recorded the dry matter production of 261.25, 213.60 and 258.70 g pot⁻¹, respectively. However, the lowest dry matter production (168.90 g pot⁻¹) was recorded with control (T1).

The increase in dry matter production with higher dose of nitrogen, phosphorus and potassium brings luxuriant growth further increased NPK uptake resulted in higher number of leaves, leaf area index and greater accumulation of nutrients, which in turn contributed to higher plant dry weight (Singh et al., 1979). This was closely followed by treatment T9 (464.79 g pot⁻¹), which was received coir pith compost, bone meal powder and panchagavya. This was due to the functions of organic nutrients brought about the increased plant height, number of tillers as well as leaves per plant up to the maximum extend and thereby increased dry matter accumulation per plant.

**CONCLUSION**

Based on the results of the pot-culture experiment, it can be concluded that application of 100%RDF (N: P₂O₅: K₂O @ 40:30:50 kg ha⁻¹) recorded the highest plant height, number of leaves plant⁻¹, LAI, chlorophyll content and dry matter production. This was on par with application of T9 – CPC+BMP+PG to barn yard millet grown in sandy loam soil.
